Active power factor correction (PFC) refers to the method of increasing power factor (PF) by using active electronic circuits with feedback that control the shape of the drawn current. There are many commercial PFC controllers that can accomplish this task. Let us first quickly review why we need to do it anyway.

### Active Power Factor Correction

Conventional active power factor correction (PFC) converters are using classical PI controllers to carry out power factor correction. As the voltage input to the converter is fluctuating, a PI controller with nonlinear gain is proposed for the control of the supply current.

What Is Power Factor Correction? Power Factor (Cos  $\phi$ ) is the ratio of True Power (kW) to Apparent Power (kVA) and is used as an indication of how efficiently an industrial or commercial site is operating. The closer the Power Factor is to unity (1), the more efficiently a site is said to be operating.

Digital power factor correction control design using Simulink <sup>®</sup> lets you make use of multirate simulation to design and tune digital control algorithms, enabling you to tailor the input current waveforms, thus keeping losses low while improving the power quality to a desired value. This approach also enables you to test and verify controllers in the presence of varying loads and input voltages before deploying the control algorithms on hardware.

### Power Factor Correction - MATLAB & Simulink

Power Factor Correction (PFC) The technique of increasing the PF towards value "1" of an electrical system is called Power Factor Correction (PFC). Ideally, current and voltage waveforms should be in phase with one another and all the electricity drawn from the AC mains should be utilized effectively.

### Power Factor - Power Triangle, Types, PFC, Applications ...

Power Factor Correction is a circuit design technique to increase the power factor of a device so that it approaches 1, or unity power factor. Although computer power supplies draw only a fraction of their full capacity during it's steady state(normal operation), PFC power supplies have the potential to draw their full capability during initial inrush.

Switching power supplies without power factor correction draw current in short, high-magnitude pulses. These pulses can be smoothed out by using active or passive techniques. This reduces the input RMS current and apparent input power, thereby increasing the power factor. The power factor correction shapes the input current in order to maximize the real power from the AC supply.

Active power factor correction can be single-stage or multi-stage. In the case of a switched-mode power supply, a boost converter is inserted between the bridge rectifier and the main input capacitors. The boost converter attempts to maintain a constant voltage at its output while drawing a current that is always in phase with and at the same ...

The traditional means of correcting power factor for the typical lagging circuit is by installing capacitance to generate some of the reactive power required by the load so as to remove the necessity of the supply from providing it. There are two configurations available for capacitance installation: series and shunt connection.

Active power factor correction is necessary in order to meet those specifications, and one of the cheapest and most common ways to implement active power factor correction is by using a boost PFC converter. The boost PFC converter uses a switching element to force the input AC current to be sinusoidal and in phase with the input voltage.
