Description. This animation describes a genetic engineering technique called DNA cloning, which can be used to make bacteria express a foreign gene, typically from another species. During DNA cloning, a new gene is inserted into a loop of bacterial DNA called a plasmid. As shown in the animation, the plasmid is first cut with a restriction enzyme so that the gene of interest, which is isolated from another organism, can be inserted into the loop.

DNA Cloning with Plasmids - HHMI BioInteractive
Cloning a gene into a vector such as a plasmid is a method widely used in molecular biology and biochemistry laboratories for the purpose of transferring the gene into another organism.

Minimally, lab-created plasmids have an origin of replication, selection marker, and cloning site. The ease of modifying plasmids and the ability of plasmids to self-replicate within a cell make them attractive tools for the life scientist or bioengineer. The above plasmid map and table outline the common engineerable features of plasmids.

Plasmids are circular pieces of DNA that exist outside the main bacterial chromosome and carry their own genes for specialized functions. In genetic engineering, plasmids are one means used to introduce foreign genes into a bacterial cell. To understand how this might work, consider the plasmid below.

FAQ. Addgene is offering Cloning Grade DNA (cgDNA) for over 200 plasmids in our collection. The plasmids available in this format include a variety of popular plasmids and backbones with high cloning potential. By making these plasmids available as cgDNA, we hope to aid scientists who want to immediately start cloning upon arrival of their plasmid from Addgene - reducing the time to experiments by removing the amplification and extraction steps required when one receives plasmids in ...

The source of the insert for cloning may be genomic DNA, a portion of another plasmid, or a linear DNA fragment. Regardless of the type of source DNA, a common first step in preparation of the insert is to perform restriction digestion to generate compatible ends for subsequent splicing into the vector.

In a PNAS paper entitled “ Construction of Biologically Functional Bacterial Plasmids In Vitro, ” my colleagues A. C. Y. Chang, H. W. Boyer, R. B. Helling, and I reported in November 1973 that individual genes can be cloned and isolated by enzymatically fragmenting DNA molecules, linking the pooled fragments to autonomously replicating circular bacterial genetic elements known as plasmids, and introducing the

Scientists working in Boyer ' s lab recognized the need for a general cloning plasmid, a compact plasmid with unique restriction sites for cloning in foreign DNA and the expression of antibiotic resistance genes for selection of transformed bacteria. In 1977, they described the first vector designed for cloning purposes, pBR322 (20).
