cortex situated at the frontal lobe. Motor neurons are found in column groups called "colonies". When a single motor neuron in a colony is activated, the other neurons get excited as well, causing the movement of muscles. Each colony has a specific movement under its control.

The Senses and the Somatic Nervous System. In this module, we consider two types of cells: one that relays information to the central nervous system (brain) for interpretation and a second set, motor neurons which relay information away from the central nervous system to govern voluntary movement. The input pathway to the brain is mediated by specific cells called senses.

Neural Manifolds for the Control of Movement The analysis of neural dynamics in several brain cortices has consistently uncovered low-dimensional manifolds that capture a significant fraction of neural variability. These neural manifolds are spanned by specific patterns of correlated neural activity, the “neural modes.”

For this reason, Dr. Montessori began using the “Walking on the Line” as a Practical Life exercise. This exercise helps the child control his body, develop balance and perfect equilibrium, as well as to strengthen the mind’s control of its body’s movements.

We discuss a model for neural control of movement in which the time-dependent activation of these neural modes is the generator of motor behavior. This manifold-based view of motor cortex may lead to a better understanding of how the brain controls movement.

*Novel population of neurons identified that control ...*

The corticospinal tract is the main pathway for control of voluntary movement in humans. There are other motor pathways which originate from subcortical groups of motor neurons (nuclei). These pathways control posture and balance, coarse movements of the proximal muscles, and coordinate head, neck and eye movements in response to visual targets.

*The Anatomy of Movement - Brain Connection*

The central nervous system structures that control movement have a hierarchical organization. 2. The spinal cord is the most caudal and simplest level of the movement control hierarchy. 3.
