Phase unwrapping refers to the process of recovering the absolute phase ϕ from a wrapped phase ψ . Phase unwrapping arise in many applications, such as wavefront measurements in interferometry, field mapping in magnetic resonance imaging, the interferometry SAR process, measurements in adaptive optics and even a deflectometry. Gaining attention for a long time, many algorithms have been developed in relation to phase unwrapping problem.

The phase unwrapping is performed using segment-wise, block-wise and pixel-wise phase unwrapping algorithms. The errors in phase unwrapping are shown in figures 3.17 (b)-(d), respectively. The effects of segment-wise, block-wise and pixel-wise methods of phase unwrapping are clearly visible in the error maps.

The algorithm has two main steps: 1. Phase unwrapping: we input two (or more) different frequency interferograms (of the same scene), which provides an extension of the $[-\pi, \pi]$ ambiguity interval and, consequently, an increasing of the phase rates that still allow unwrapping to be a well-posed problem.

In this paper, we present a noniterative simultaneous phase unwrapping and denoising algorithm for phase imaging, referred to as SPUD. The proposed method relies on the least squares discrete cosine transform (DCT) solution for phase unwrapping with an additional sparsity constraint on the DCT coefficients of the unwrapped solution.

However, the phase distribution is computed as modulo 2π of the absolute phase due to inverse tangent operation, which makes the phase unwrapping indispensable. The reliability of phase unwrapping depends heavily on the quality of the phase pattern. If the fringe patterns recorded in phase shifting or Fourier transform interferometry setups are not filtered before phase demodulation, the corresponding phase pattern carry the speckle noise that adversely affect the subsequent phase ...

sence of discontinuities. The phase unwrapping equipped with this adaptive LPA prefiltering yields very good accuracy of the phase reconstruction, quite often overcoming the state-of-the-art algorithms developed for noisy phase unwrap. The polynomial modeling is a popular idea for both wrapped phase denoising and noisy phase unwrap.

Most of existing unwrapping algorithms implement denoising operations first to obtain noise-free phases and then conduct phase unwrapping pixel by pixel. This approach is sensitive to spikes and prone to unreliable results in practice. In this paper, a robust unwrapping algorithm based on the non-subsampled contourlet transform (NSCT) is developed.

Abstract: In the traditional processing flow of interferometric synthetic aperture radar (SAR) technique, the processing of phase is conducted via two separated and successive steps, i.e., phase denoising and phase unwrapping. That is to say, first, wrapped phases without noise are generated, and then, the true phases without 2π -ambiguities are reconstructed (here and in the rest of this paper, true phase refers to the information-induced unwrapped phase without noise).

The paper attacks absolute phase estimation with a two-step approach: the first step applies an adaptive local denoising scheme to the modulo- 2π noisy phase; the second step applies a robust phase unwrapping algorithm to the denoised modulo- 2π phase obtained in the first step. The adaptive local modulo- 2π phase denoising is a new algorithm based on local polynomial approximations.

Abstract. The phase of an image obtained with many magnetic resonance imaging techniques is related to some physical variable of interest. This phase needs to be unwrapped, which is complicated by the presence of noise and multiple objects of irregular shape. A new two-dimensional phase unwrapping algorithm is presented, along with simulation results. © 1992 Academic Press, Inc.
