Abstract A number of ring-extended DNA adducts resulting from reaction of  $\alpha,\beta$ -unsaturated aldehydes, of their epoxides, with DNA bases have been characterized in recent years. These adducts can...

By using a gene-targeted random DNA adduction approach, we have recently shown that chloroacetaldehyde, a metabolite of vinyl chloride, induces mutations predominantly at cytosines under conditions in which both ethenoadenine (epsilon A) and ethenocytosine (epsilon C) are formed.

Our recent results show that ethenocytosine (epsilon C), a noninstructional exocyclic DNA lesion induced by vinyl chloride, may have unusual mutagenic properties. To obtain more definitive experimental evidence for the observed effects, we have introduced a single epsilon C residue at a specific site of coliphage M13AB28 replicative form DNA by a "single-stranded linker-ligation" technique.

We propose that in DNA under physiological conditions, DEB alkylates the N-1 position of adenine in DNA to form N1-(2-hydroxy-3,4-epoxybut-1-yl)-adenine adducts, which undergo an S N 2-type intramolecular nucleophilic substitution and rearrangement to give 3 (minor) and 4 (major). Formation of exocyclic DEB-adenine lesions following exposure to 1,3-butadiene provides a possible mechanism of mutagenesis at the A:T base pairs.

*Exocyclic Deoxyadenosine Adducts of 1,2,3,4 Diepoxybutane ...*  
Exocyclic alkylamino purine adducts, including N 2-ethyldeoxyguanosine, N 2-isopropyldeoxyguanosine, and N 6-isopropyldeoxyadenosine, occur as a consequence of reactions of DNA with toxins such as the ethanol metabolite acetaldehyde, diisopropylnitrosamine, and diisopropyltriazeno. However, there are few data addressing the biological consequences of these adducts when present in DNA.

In this report, we have examined the generation of exocyclic DNA adducts, indicated from M 1 dG, a biomarker of oxidative stress and LPO, in a murine model of NASH [23]. The hepatic levels of M 1 dG adducts have been measured using the 32P-DNA postlabeling assay [10,13], a highly sensitive technique widely employed for the analysis

The volume includes sections on ultrasensitive ...

*Exocyclic DNA Adducts in Mutagenesis and Carcinogenesis*  
Acrolein is a highly reactive alpha,beta-unsaturated aldehyde and is known to react with DNA forming exocyclic acrolein-deoxyguanosine adducts (Acro-dG). These aldehyde-DNA lesions may play a role in mutagenesis, carcinogenesis, and neurodegenerative diseases. In the present work, we described the development and evaluation of a highly sensitive and selective capillary liquid chromatography nanoelectrospray isotope dilution tandem mass spectrometry method for quantitatively analyzing Acro-dG ...

*Development of a method for quantification of acrolein ...*  
Acrolein reacts with DNA at guanine residues to form the exocyclic adduct, 8-hydroxypropanodeoxyguanosine (HOPdG). Acrolein is mutagenic, and a correlation exists between HOPdG levels in Salmonella typhimurium treated with acrolein and a resultant increase in mutation frequency.

DNA adducts and oncogene activation in AIA-induced tumors. Specific mutations are critical for the activation of oncogenes and inactivation of tumor suppressor genes associated with carcinogenesis (214- 216). Several studies have examined AIA-induced tumors for mutations in genes including p53, Ki-ras and Ha-ras, Apc and B-catenin (217- 230). Among the mutations detected in these genes, guanine base mutations occurred with the highest frequency, suggestive of the involvement of AIA-DNA ...
