One essential part of Linux kernel development is debugging. In user space we had the support of the kernel so we could easily stop processes and use gdb to inspect their behavior. In the kernel, in order to use gdb we need to use hypervisor like QEMU or JTAG based hardware interfaces which are not always available.

The kernel debugger kgdb, hypervisors like QEMU or JTAG-based hardware interfaces allow to debug the Linux kernel and its modules during runtime using gdb. Gdb comes with a powerful scripting interface for python. The kernel provides a collection of helper scripts that can simplify typical kernel debugging steps.

Debugging kernel and modules via gdb - The Linux Kernel ...

The Linux kernel does not export a stable, well-defined ker-nel interface, complicating the development of kernel-level services, such as device drivers and file systems. While there does exist a set of functions that are exported to external modules, this set of functions frequently changes, and the functions have implicit, ill-documented preconditions.
